

Cross-Commodity Risk Pack

Gas + Carbon -> Power Curve Implications | 19 June 2026

Today's Monitor Metrics

TTF Front-Month	EU Gas Storage Fill	EU ETS Carbon (EUA)	Clean Spark Spread	German Power DA	EU LNG Send-Out
42.07	45.82	76.14	5.15	108.18	3669.3
EUR/MWh	%	EUR/tonne	EUR/MWh	EUR/MWh	GWh/day

AI-Generated Trading Brief

This morning, the gas market is showing signs of easing tightness, with TTF Front-Month at 42.07 EUR/MWh and EU Gas Storage Fill at 45.82%, still relatively low but supported by robust LNG send-out of 3669.3 GWh/day. The recent 6% price tumble following the US-Iran peace deal has alleviated some pressure, but we remain cautious given the storage deficit.

On the carbon front, EUA prices are holding firm at 76.14 EUR/tonne, with the Top EU Party pushing for carbon market changes to protect industries, which could introduce policy risk. The proposed extension of free permits for local investments may also influence EUA price dynamics.

The power curve is looking relatively healthy, with a Clean Spark Spread of 5.15 EUR/MWh and German Power DA at 108.18 EUR/MWh, indicating decent margins for gas-fired power generation. Today, we're watching the potential impact of any further news on the Iran war and its effect on gas prices, as well as any developments on the EU carbon market policy front, which could introduce volatility into the market.

TTF Natural Gas - 3 Month Price History

EU Gas Storage: 2026 vs 2025

Metric Rationale & Methodology

TTF Front-Month (EUR/MWh)

The European gas benchmark. Gas-fired power plants set the marginal price of electricity across most hours in Europe. TTF is the primary input cost for these plants - every move in TTF flows directly into power curve pricing.

EU Gas Storage Fill (%)

The physical tightness signal. Storage fill vs the same date last year tells you how much winter supply buffer Europe has. Currently 8.7pp below 2025 levels, which means the market is more exposed to a cold snap or LNG supply disruption than the current TTF price implies.

EU ETS Carbon / EUA (EUR/tonne)

The carbon cost overlay. Each MWh of gas-fired generation emits ~0.202 tonnes of CO₂, each requiring an EU Allowance. At EUR 75/t, carbon adds ~EUR 15/MWh on top of the gas cost. ETS reform in 2026 and CBAM implementation are structural tailwinds for EUA prices.

Clean Spark Spread (EUR/MWh)

DERIVED METRIC - Formula: German Power DA - (TTF x 7.5/3.6) - (EUA x 0.202). Here 7.5 is the heat rate in GJ/MWh (energy input per MWh of electricity), divided by 3.6 to convert GJ to MWh, giving ~2.08 MWh of gas per MWh of power (equivalent to ~48% CCGT efficiency). 0.202 is the CO₂ emission factor in t/MWh. Positive spread = gas plants profitable and dispatching. Negative = gas pushed out of merit order.

German Power DA (EUR/MWh)

The spot power benchmark. Clears after all generation sources have bid in. The gap between DA and the forward curve (Cal-27 ~EUR 93/MWh) signals the market's structural view on tightness. A persistently high DA vs forward suggests the market expects current tightness to ease over time.

EU LNG Send-Out (GWh/day)

The flow signal. Europe is structurally dependent on LNG imports since 2022. Daily send-out from receiving terminals is the fastest supply signal available - a drop here due to geopolitical disruption or Asian demand competition translates to TTF upward pressure within days.
